Quality of life psychotics during the aerial bombing of Yugoslavia

G. Mandic-Gajic*, R. Samardzic, Z. Spiric, M. Preradovic. *Military Medical Academy, Department of Psychiatry, Belgrade, Yugoslavia*

Background: Quality of life has been defined as the subjectively and objectively measured 'goodness of life' including health, physical environment, and material circumstances.

Objectives: The quality of life was evaluated in the group of chronic psychotic patients who attended psychosocial club in Day unit more than 6 months before and during the bombing in 1999.

Method: We used Global Assessment of Functioning Scale (GAF) as measured of quality of life in sample of 34 patients. The most of them were schizophrenics (61,8%), with mean aged of 34,2 years old, unemployed, single, living with parents, with mean aged of 22,8 years of onset of illness.

Results: Mean GAF score was $54,6 \pm 4,2$ before and $55,1 \pm 4,6$ after the bombing without statistical difference ($p < 0,05$) in the level of moderate symptoms and difficulty in functioning.

Conclusions: The majority of our patients had more intensive interpersonal relations and used active coping styles during bombing. It is confirmed that more frequent therapeutic contact and maintains therapy with neuroleptics help to prevent relapse of psychotic disorders.

Prader-Willi syndrome and atypical psychoses

W.M.A. Verhoeven*, L.M.G. Curfs, S. Tuinier. *Vincent van Gogh Institute for Psychiatry, Venray, The Netherlands*

More than 20 years after the original identification of Prader-Willi Syndrome (PWS), the genetic abnormality appeared to comprise del15q11-13. Subsequently, it was recognized that in a substantial number of PWS patients, deletions were found on the chromosome 15 that originated from the father only. Consecutive research demonstrated that the phenomenon of genomic imprinting is also involved in the genetic etiology of PWS, in that maternal uniparental disomy (UDP) is present in approximately 25 percent of the patients.

Concerning the pathophysiology of PWS, appetite control, undersized sex organs, insufficient growth during puberty, temperature instability and altered pain threshold as well as disturbances in the sleep-wake cycle, all witness the existence of a hypothalamic disorder.

With respect to behaviour, a variety of behavioural difficulties may become prominent which include temper tantrums, stubbornness, impulsivity, mood lability, obsessive rituals, self-injury especially through skin picking, emotional and psychological problems as well as sleep abnormalities. Regarding psychopathology, emotional turmoil, anxieties, confusion, mood swings and psychotic features have been reported.

The present study includes 16 patients who were referred to the first author because of psychotic deterioration and increase of behavioural abnormalities. The most prominent symptoms were: emotional turmoil, anxiety, confusion, rapid mood swings, hallucinatory experiences, paranoid ideation and an increase of obsessive rituals. Psychotic episodes were characterized by subacute onset, short duration and full recovery upon treatment with mood stabilizing agents. Thus, this type of psychosis meets the ICD-10 criteria of cycloid psychosis.

Evolution of epileptic psychosis

B.A. Kazakovcev*, E.L. Maxutova, L.V. Sokolova. *Moscow Research Institute of Psychiatry, Department of Epilepsy, Russia*

The term "Schizoepilepsia", which was widely spread at the beginning of 20 century, is not meeting during the last years. The cause of it is not only the new methodology of psychopathologic diagnosis among epileptic patients, but it connected with pathomorphism of clinic and disease, which was happened especially among young patients. Clinic-population analysis of 2542 case records of epileptic patients for 10 years was held. Among hospitalized patients of special epileptic department of Moscow Scientific Institute of Psychiatry the specific gravity of patients with acute and chronic psychosis decrease from 17 % in 1991–1992 to 10 % in 2000. Depressive-paranoid, depressive-hypochondriac and paranoiac ideas are predominate among leading psychopathologic syndromes. Tendency to growth of frequency of nonpsychotic and personality disorders is watching clearly. Syndromes of psychic automatism's and catatonia are meeting seldom.

Conclusion: Comparative clinic-statistical analysis frequency of psychosis among epileptic patients certificate about tendency to reduce of its specific gravity among patients of psychiatric hospitals. Medicaments pathomorphism which connected with widening spectrum of effective anticonvulsant with normotymic and prophylactic psychotropic effects may be a certain determined factor.

Period of adolescence – psychiatric differentiation of symptomatology

L. Leposavic¹*, Z. Barac², A. Latic³, J. Barisic-Rojnic¹, G. Nikolic-Balkoski¹, S. Milovanovic¹. ¹*Institute of psychiatry, Belgrade;* ²*Dispensary of Mental Health, Zemun;* ³*Clinic of Neurology and Psychiatry for Children and Adolescents, Belgrade, Yugoslavia*

The period of adolescence is of special importance because some of serious psychiatric disorders (e.g. endogenous psychoses) begin at this age. Clinical picture which manifests these disorders is often "introduced" as a variation of adolescent crisis or specific psychopathological disorders characteristic for the period of youth. It is necessary, according to clinical experience, to make essential difference, in spite of their phenomenological similarities, between psychopathology of adolescent crisis and psychopathology which only coincides to adolescent crisis but which acted as a promoting factor for deeper psychopathological manifestation. In this paper the authors pay special attention to psychoses of developmental period, as the most severe and the deepest degree of psychopathological disorders, and which can be of schizophrenic and affective type. Marginal cases, like disharmony between and inside the structure and their functions with expresses phenomena of neurotic and psychotic type, are also considered.
