

learning styles. This pilot study demonstrated such interactive components of Psychiatry teaching continue to be well received and can be effectively delivered remotely. Such sessions also serve to promote inclusivity, linking those who are geographically distant in addition to the visual learner and the neurodiverse. We aim to incorporate these dynamic teaching sessions into our online induction programs and disseminate Intelligent Tutorials to our remote and rural learners throughout Scotland.

Pilot study of the use of handheld 6-lead ECG for patients on acute general adult mental health wards who refuse traditional 12-lead ECG

Aims. To assess patient and clinician acceptability of handheld 6-lead ECG, for obtaining information about cardiac rhythm and electrical intervals, in acute general adult mental health ward inpatients who refuse traditional 12-lead ECG.

Background. In a previous audit of patients admitted to four acute general adult mental health wards, we found that 1 in 4 patients refused 12-lead ECG for at least two weeks, with 1 in 6 refusing throughout their entire stay. ECG refusers were significantly more likely to have a psychotic illness than non-refusers and were thus more likely to benefit from medications that carry a risk of prolonging the QT interval. Less invasive, handheld, 6-lead ECG, which includes measurement of lead II (the lead used to define traditional QT-interval cut-off values) is available on the NHS supply chain. Whilst not providing the full range of information that 12-lead ECG is able to provide, handheld 6-lead ECG might be an acceptable alternative in patients who would otherwise never have any form of ECG performed.

Method. We developed a Standard Operating Procedure for use of handheld 6-lead ECG and provided training for junior doctors on the four wards that were the subject of our original audit. These doctors were then able to offer the device to patients on their wards who refused 12-lead ECG. Doctors completed a short feedback form each time a handheld ECG was offered.

Result. So far, handheld 6-lead ECGs have been offered to 17 patients who refused 12-lead ECGs. Mean age (\pm SD) was 36.1 (\pm 12.6) years, and 4 of these patients were female. 13 patients (76%) accepted a handheld ECG. One of these attempts failed due to patient agitation. Attempts took a mean of 7 (\pm 5.4) minutes. 54% of recordings were described as “very easy” by clinicians, whereas 15%, 23% and 8% were described as “somewhat easy”, “intermediate”, and “somewhat difficult”, respectively. Clinician difficulties focussed on patient movement with impact on electrode contact and trace quality. Where answered ($N = 10$), 90% of patients stated they would recommend a handheld ECG to others. Patients liked the speed of the process, that it felt “less scary”, and that it was less invasive and did not involve removing clothing.

Conclusion. Our initial findings from this pilot suggest that handheld 6-lead ECG may be acceptable, both to clinicians and patients, as a means of obtaining information on cardiac rhythm and electrical intervals for patients who refuse 12-lead ECGs.

Screening for ADHD in male medium secure psychiatric services

Scott Broadhurst* and Kathryn Swindell

The Spinney Hospital

*Corresponding author.

doi: 10.1192/bjo.2021.89

Aims. Roughly 25% of the prison population are known to meet the criteria for attention-deficit/hyperactivity disorder (ADHD), a five-fold increase on the general population. Medium secure psychiatric services receive a high percentage of referrals from the prison service. ADHD has primary symptoms of inattention, hyperactivity and impulsivity. Untreated ADHD could clearly have a detrimental impact on the effectiveness of therapeutic interventions, as well as increasing incidents of violence, aggression and other transgressive behaviours.

There are two aims: To screen the medium secure services population at the Spinney Hospital, Atherton, UK for ADHD, using a validated screening tool. This would generate candidates for further structured clinical assessment for ADHD; To implement ADHD screening as a feature of the Admission Care Plan within medium secure services at the Spinney.

Method. The study population is the medium secure service at The Spinney Hospital, Atherton. At the time of study this was 52 male service users.

The team members have evaluated several screening tools. The tool eventually chosen was the B-BAARS, which is a simple 6-question tool that is validated for use in adults. The tool takes around 1 minute to complete. All 52 service users were screened between 20/01/2021 and 30/01/2021.

Result. 1 of the 52 service users had a current diagnosis of ADHD and was being treated with medication. 3 of the 52 service users had childhood diagnoses of ADHD that had lapsed in adulthood and who were untreated. Of the remaining 51 service users without a current diagnosis of ADHD, 9 were positive on screening as worthy of further assessment (17.65%). Assessments of the 9 service users positive in screening will be completed by medical and psychology disciplines.

Conclusion. There appears to be clear merit for routine screening for ADHD within medium secure psychiatric services, given the service user population and the results described above. As a result of this survey, within The Spinney Hospital the B-BAARS will be incorporated into the Admission Care Plan of all new admissions to medium secure services as a Quality Improvement Intervention. Over time this will be re-audited and there will be assessment of any impact on incidents and positive engagement with activities.

Distinguishing vulnerable clients from psychotic patients with follow-up mortality data

Aggrey Burke

Cope mental health foundation

doi: 10.1192/bjo.2021.90

Aims. The aim of the present study is to determine whether vulnerable non-psychotic clients presenting in court proceedings do not share the same mortality profile as psychotic patients in similar environments. It is hypothesised that the two display quite separate mortality profiles.

Background. The increased mortality of psychiatric patients and prisoners has been documented but less is known of the outcomes among other vulnerable populations.

The population for study is a consecutive series of assessments in court proceedings of carers of children at risk and violent offenders.

Method. Assistants not involved in the initial assessments transferred data from case notes and this material was transferred to computer files. Statistical analysis SPSS19

Formal psychiatric diagnoses were those agreed in court proceedings. National mortality records were searched and copies of death certificates obtained. A small number of cases known to have returned overseas were excluded. 772 cases were studied. One in five were assessed in prison, twice as many gave a history of violent criminal behaviour. Over a half suffered abuse or neglect or admitted to being unhappy in childhood. Three subgroups have been identified: Vulnerable with no psychotic illness(60%), psychosis with no evidence of personality disorder or of mixed psychosis(18%), linked psychosis(22%). It was found that demographic variables, deprivation factors, adverse childhood experiences and outcomes and clinical variables are in excess among linked psychotics compared with other groups. Linear regression of unnatural death among psychotic patients identifies five risk factors. The distribution of high-risk factors among linked psychosis is more than twice that found in other groups.

Result. Natural mortality is most evident among clients suffering from psychosis without personality disorder or mixed disorder. Unnatural mortality is more than 10 times greater among patients with linked psychosis, compared with those with no psychosis and four times greater than other psychoses. Risk factors for unnatural mortality are: physical illness, stressful relationship, violence to self or others, detained and history of behaviour disorder.

Conclusion. The findings of the present study demonstrate that vulnerable clients without psychosis are less likely to die by unnatural causes than clients who suffer psychosis coexisting with personality disorder or mixed psychosis. The null hypothesis is upheld. The findings suggest that risk assessment of vulnerable populations should take account of risk factors of unnatural death which have been identified in this study.

An audit of vitamin D monitoring and management of deficiency in women's secure services

Claire Bustin^{1*}, Shay-Anne Pantall² and Jeremy Rampling²

doi: 10.1192/bjo.2021.91

Aims. To audit the investigation, identification and treatment of vitamin D deficiency within Women's Secure Services.

Background. It has been suggested that vitamin D and vitamin D deficiency may play a role in the pathogenesis of psychiatric illness. There is evidence that vitamin D inadequacy is prevalent among patients in long-term hospital settings. Patients within secure hospitals are considered to be at high risk due to their often lengthy admissions, having been transferred from other hospital or prison settings. Ardenleigh in Birmingham is a blended female secure unit. Here we present the findings of an audit, completed in 2019, of vitamin D monitoring and treatment in this service.

Method. A retrospective review of electronic patient records, for all inpatients admitted within women's secure services at Ardenleigh as of 1st September 2019 (n = 27). Standards were based on the Trust accepted guidelines for management of vitamin D deficiency.

Result. Key findings included:-

The majority of inpatients were Caucasian (44%) and African-Caribbean (41%). Median age was 31 years (range 20–56).

Approximately two-thirds (60%) had been in hospital for over a year.

89% of patients had their vitamin D level checked at some point during admission.

Of those checked, 25% were tested within 1 week of admission. Seven patients were tested after being in hospital for over one year (30%).

Only 25% of patients tested were found to have adequate vitamin D levels. Nine patients were found to have insufficient levels of vitamin D (37.5%) or deficiency (37.5%).

89% of those identified as requiring treatment were prescribed supplementation, of which the majority was prescribed at the correct dose for the appropriate duration (94%). One patient refused treatment. Of those with sufficient levels, 67% were prescribed ongoing maintenance treatment due to previously detected deficiency.

Of those found to have sufficient vitamin D in the last 12 months (n = 14), 71% were continued on maintenance treatment.

Conclusion. We identified a high prevalence of vitamin D insufficiency in women admitted to secure services. Testing was delayed for a number of patients from the point of admission. However, once identified, the vast majority of those in need of treatment were managed appropriately by the medical team. We advise that vitamin D be considered an essential routine blood test at the point of admission to minimise delays in identifying those with deficiency and establishing necessary supplementation.

A new handover protocol between old age admission and rehab wards

Aileen Carmen*, Thanurshan Mahenthiran, Jemma Hazan and Ioana Popescu

Barnet Enfield and Haringey Mental Health Trust

doi: 10.1192/bjo.2021.92

Aims. Efficient handovers are integral to patient care. Challenges to handover for wards include high patient turnover and varied handover approaches between wards, as well as admissions out of hours. Patients on Old Age Wards often have multiple comorbidities and can deteriorate rapidly without coordinated care. Our focus was on improving handover of patients transferred between the Old Age Admissions Ward and Rehabilitation Ward. We aimed to create a ward handover protocol to improve compliance with documenting a pretransfer plan and ensure there was an 80% compliance with completing this plan within 3 months.

Method. An MDT discussion took place in order to explore change ideas. Questionnaires were filled out post implementation of protocol. A handover proforma was designed to capture important patient data and continuing plans. A PDSA cycle was designed to deliver a structured handover.

Per patient measures were collected including: whether a handover took place, recording of current medical and psychiatric issues, documentation of plan and was the plan put into action or reviewed.

MDT feedback was collected on satisfaction with the protocol and handover process using open questions and Likert scale.

Result. Prior to the establishment of the proforma there was no verbal or written handover between wards. In 28% of cases prior to the intervention, blood results were checked and
