

# LIE GROUP VALUED INTEGRATION IN WELL-ADAPTED TOPOSES

ANDERS KOCK

In the context of synthetic differential geometry, we prove that group valued 1-forms on the unit interval are exact, provided the group in question is a Lie group. This exactness is the basic assumption in a previous paper by the author on differential forms with values in groups.

## 0. Introduction.

We consider the standard well adapted topos models for synthetic differential geometry, and prove the validity here of a fundamental Theorem of differential geometry, namely that, for  $G$  a Lie Group,

\*  $G$ -valued 1-forms on  $R$  (or on  $[0,1]$ ) are exact.

(the classical (well known) version of this Theorem has a less simple formulation, and is stated in the beginning of Chapter 3.) I have expounded the meaning of \* in several articles [8], [9], [10].

The main technical tool for proving validity of \* in the topos models is a generalization of a Theorem of O. Bruno [2] from the 1-variable case to the  $n$ -variable case, and for this generalization, we

resort to convenient vector space theory [6], [14], [12].

The well-adapted models we consider are  $Z$ ,  $F$  and  $G$  of [4], [15], whose sites of definition have as objects  $C^\infty$ -rings  $C^\infty(\mathbb{R}^n)/I$  with  $I$  an arbitrary, respectively  $W$ -determined, respectively germ determined ideal (terminology of [7]). (The arguments and results we present are independent of which subcanonical Grothendieck topology we consider.) Any of the three toposes will be denoted  $E$ . The category  $Mf$  of manifolds is embedded into  $E$ , in the standard way,  $M \in Mf$  being represented by the ring  $C^\infty(M)$ . We omit the embedding  $i$  from the notation, except that we write  $R$  for  $i(\mathbb{R})$ .

1. Congruence modulo ideals.

Let  $I \subseteq C^\infty(\mathbb{R}^P)$  be an ideal, fixed for this section. Let  $M$  be a manifold (or any other set structured with a  $C^\infty$ -ring  $C^\infty(M)$  of functions  $M \rightarrow \mathbb{R}$ , in particular,  $M$  may be a convenient vector space). We let  $I(M)$  denote the equivalence relation on  $C^\infty(\mathbb{R}^P, M)$  given by

$$f \equiv g \pmod{I(M)} \text{ if and only if for all } \phi \in C^\infty(M), (\phi \circ f - \phi \circ g) \in I$$

or equivalently, if and only if

$$(1.1) \quad C^\infty(M) \begin{array}{c} \xrightarrow{f^*} \\ \xrightarrow{g^*} \end{array} C^\infty(\mathbb{R}^P) \longrightarrow C^\infty(\mathbb{R}^P)/I$$

commutes.

This we call weak congruence mod  $I(M)$ , or just mod  $I$ . If  $X$  is a convenient vector space, we let  $I(X)$  denote the linear subspace of  $C^\infty(\mathbb{R}^P, X)$  spanned (purely algebraically) by functions of the form

$$(1.2) \quad h(t) \cdot k(t) \quad t \in \mathbb{R}^P$$

with  $h: \mathbb{R}^P \rightarrow \mathbb{R}$  in  $I$  and  $k: \mathbb{R}^P \rightarrow X$  arbitrary smooth.

Two maps  $\mathbb{R}^P \rightarrow X$  will be called strongly congruent mod  $I(X)$ , or just mod  $I$ , if their difference belongs to  $I(X)$ .

To compare the two notions where it makes sense (Proposition 1.3 below), we shall use the following unsurprising Lemma from convenient vector space theory.

LEMMA 1.1. Let  $G: X \longrightarrow Y$  be a smooth map between convenient vector spaces. Then there exists a smooth  $H: X \times X \times \mathbb{R} \longrightarrow Y$  such that

$$(1.3) \quad G(x + \lambda \cdot y) = G(x) + \lambda \cdot H(x, y, \lambda)$$

for all  $x, y \in X$  and  $\lambda \in \mathbb{R}$ .

Proof. Consider the function  $H$  defined by

$$H(x, y, \lambda) = \int_0^1 df_{x+s\lambda y}(y) ds .$$

It will serve in (1.3), by the standard (Hadamard) calculation. It depends smoothly on  $(x, y, \lambda)$ ; for,  $df_x(y)$  depends smoothly on  $(x, y)$  (see [14], Satz p.299, or [6], Theorem 6.2), and integration preserves smoothness (see for example [12], Proposition 2.6).

Let  $X$  and  $Y$  again denote convenient vector spaces; then

PROPOSITION 1.2. Let  $f, g: \mathbb{R}^p \longrightarrow X$  be strongly congruent mod  $I$ , and let  $G: X \longrightarrow Y$  be smooth. Then  $G \circ f$  and  $G \circ g$  are strongly congruent mod  $I$ .

Proof. By assumption,  $g(t) = f(t) + \sum h_i(t)k_i(t)$  with  $h_i$  and  $k_i$  as in (1.2). We may remove one  $h_i(t) \cdot k_i(t)$  summand at a time, so it suffices to consider the case

$$g(t) = f(t) + h(t) \cdot k(t) .$$

Let  $H$  be as in Lemma 1.1. Then since  $h(t) \in \mathbb{R}$ , we have

$$\begin{aligned} G(g(t)) &= G(f(t) + h(t) \cdot k(t)) \\ &= G(f(t)) + h(t) \cdot H(f(t), k(t), h(t)), \end{aligned}$$

and the last term is in  $I(Y)$  due to the factor  $h(t)$ .

PROPOSITION 1.3. Let  $X$  be a convenient vector space; then strong congruence mod  $I$  of maps  $\mathbb{R}^p \longrightarrow X$  implies weak congruence. For  $X$  finite dimensional, the converse holds.

Proof. The first part is immediate from Proposition 1.2 (let  $G = \phi \in C^\infty(M)$ ). For the second, let  $f$  and  $g: \mathbb{R}^p \longrightarrow \mathbb{R}^n$  be

weakly congruent mod  $I(\mathbb{R}^n)$ . For each of the  $n$  coordinate projections  $\text{proj}_i: \mathbb{R}^n \longrightarrow \mathbb{R}$ , we therefore have

$$\text{proj}_i \circ g - \text{proj}_i \circ f \in I.$$

Denote this map by  $h_i: \mathbb{R}^P \longrightarrow \mathbb{R}$ . So

$$g(t) = f(t) + \sum h_i(t) \cdot \underline{e}_i$$

where  $\underline{e}_i$  is the constant function  $\mathbb{R}^P \longrightarrow \mathbb{R}^n$  with value  $\underline{e}_i \in \mathbb{R}^n$ . Since  $h_i \in I$ , this proves strong congruence.

It is clear that strong congruence behaves well with respect to products: for maps  $\mathbb{R}^P \longrightarrow X_1 \times \dots \times X_n$  ( $X_i$  convenient), congruence mod  $I(X_1 \times \dots \times X_n)$  is tested coordinatewise, that is by testing congruence mod  $I(X_i)$  ( $i = 1, \dots, n$ ). As a corollary of Proposition 1.2, we therefore derive

**PROPOSITION 1.4.** *Let  $G: X_1 \times \dots \times X_n \longrightarrow Y$  be smooth, and let  $f_j, g_j$  be maps  $\mathbb{R}^P \longrightarrow X_j$ . If (strongly)*

$$f_j \equiv g_j \pmod{I(X_j)} \quad j = 1, \dots, n$$

then (strongly)

$$G \circ (f_1, \dots, f_n) \equiv G \circ (g_1, \dots, g_n) \pmod{I(Y)}.$$

If  $K$  is a manifold, the ideal  $I \subseteq C^\infty(\mathbb{R}^P)$  defines an ideal  $I^*$  in  $C^\infty(\mathbb{R}^P \times K)$ , namely the one spanned by functions  $h(t)k(t, x)$  ( $t \in \mathbb{R}^P$ ,  $x \in K$ , and  $h \in I$ ). Clearly, under the isomorphism

$$(1.4) \quad C^\infty(\mathbb{R}^P, C^\infty(K)) \simeq C^\infty(\mathbb{R}^P \times K),$$

$I(C^\infty(K)) \subseteq C^\infty(\mathbb{R}^P, C^\infty(K))$  corresponds to  $I^*$ .

Suppose now that we have a smooth map ('operator')

$$(1.5) \quad C^\infty(K)^n \xrightarrow{G} C^\infty(L)$$

with  $L$  a manifold. The composite

$$(1.6) \quad C^\infty(\mathbb{R}^P \times K)^n \simeq C^\infty(\mathbb{R}^P, C^\infty(K))^n \xrightarrow{G_*} C^\infty(\mathbb{R}^P, C^\infty(L)) \simeq C^\infty(\mathbb{R}^P \times L),$$

(where  $G_*$ , modulo the identification  $C^\infty(\mathbb{R}^P, C^\infty(K))^n \simeq C^\infty(\mathbb{R}^P, C^\infty(K)^n)$ , is just "composing with  $G$ ") should be considered as "applying  $G$  parameterwise in  $t \in \mathbb{R}^P$ ". Let us denote it by  $G/\mathbb{R}^P$  (or just  $G$ ). Let  $f_i$  and  $g_i$  be elements of  $C^\infty(\mathbb{R}^P \times K)$  for  $i = 1, \dots, n$ , and let  $G$  be as above (1.5). We then have

**THEOREM 1.5.** *Let  $f_i - g_i \in I^* \subseteq C^\infty(\mathbb{R}^P \times K)$ , for  $i = 1, \dots, n$ . Then*

$$G/\mathbb{R}^P(f_1, \dots, f_n) - G/\mathbb{R}^P(g_1, \dots, g_n) \in I^* \subseteq C^\infty(\mathbb{R}^P \times L).$$

(For  $n = 1$ , this is implicit in Bruno's Theorem 8, [2].)

**Proof.** The assumption means  $\hat{f}_i \equiv \hat{g}_i \pmod{I(C^\infty(K))} \forall i$ ; by Proposition 1.4,

$$G \circ (\hat{f}_1, \dots, \hat{f}_n) = G \circ (\hat{g}_1, \dots, \hat{g}_n) \pmod{I(C^\infty(L))}$$

and again this implies congruence mod  $I^* \subseteq C^\infty(\mathbb{R}^P \times L)$  for the exponential adjoints, which are the terms appearing in the Theorem.

Even when the ideal  $I \subseteq C^\infty(\mathbb{R}^P)$  is  $W$ -determined, respectively germ-determined, the ideal  $I^* \subseteq C^\infty(\mathbb{R}^P \times K)$  may not be, so to get results about the models  $F$  and  $G$  (see the introduction), we need to take the ' $W$ -radical', respectively 'germ-radial' of  $I^*$  (terminology of [7]).

It is known (see, for example [5]) that the  $W$ -radical  $\bar{J}$  of an ideal  $J \subseteq C^\infty(\mathbb{R}^k)$  is its closure in the Frechet space topology on  $C^\infty(\mathbb{R}^k)$ . An unpublished result of Penon says that the germ-radical  $\tilde{J}$  similarly is the closure of  $J$  in a finer topology on  $C^\infty(\mathbb{R}^k)$ , called the Stone-topology in [2], where this topology is described, and a sketch of Penon's result is given.

We shall need the following important result. Let  $K$  and  $L$  be manifolds, and let  $G: C^\infty(K, \mathbb{R}^n) \longrightarrow C^\infty(L)$  be a smooth operator. Then

**THEOREM.** (Frölicher [5]).  *$G$  is continuous with respect to the Frechet topologies.*

**THEOREM.** (Bruno [2]). *G is continuous with respect to the Stone topologies.*

(Frölicher in fact proves that any (plot-) smooth map between Frechet spaces is continuous. Bruno proves the Theorem quoted only when  $K$  and  $L$  are coordinate spaces and  $n = 1$ , but his proof carries over immediately.)

Using these Theorems in conjunction with Theorem 1.5 leads to the following result (with notation as in Theorem 1.5):

**THEOREM 1.7.** *Let  $(f_i - g_i) \in \bar{I}^*$  (respectively  $\tilde{I}^*$ )  $\subseteq C^\infty(\mathbb{R}^P \times K)$  for  $i = 1, \dots, n$ . Then  $G/\mathbb{R}^P(f_1, \dots, f_n) - G/\mathbb{R}^P(g_1, \dots, g_n) \in \bar{I}^*$  (respectively  $\tilde{I}^*$ )  $\subseteq C^\infty(\mathbb{R}^P \times L)$*

(For  $\tilde{I}^*$  and  $n = 1$ , this is Bruno's Theorem 8, [2].)

**Proof.** For each  $i = 1, \dots, n$ , let  $(h_m^i)_{m \in \mathbb{N}}$  be a sequence in  $I^*$  converging in the relevant topology to  $g_i - f_i$ . For each  $m$ , Theorem 1.5 applies to the  $n$ -tuple

$$(f_i, f_i + h_m^i)_{i = 1, \dots, n}$$

to give

$$(1.7) \quad G/\mathbb{R}^P(f_1, \dots, f_n) - G/\mathbb{R}^P(f_1 + h_m^1, \dots, f_n + h_m^n) \in I^* .$$

As  $m \rightarrow \infty$ , the right hand term converges to  $G/\mathbb{R}^P(g_1, \dots, g_n)$  by continuity of  $G/\mathbb{R}^P$  (which is a smooth map  $C^\infty(\mathbb{R}^P \times K, \mathbb{R}^n) \rightarrow C^\infty(\mathbb{R}^P \times L)$ , hence continuous by the Theorems quoted). So the difference is the one in the Theorem, and is a limit of expressions (1.7) in  $I^*$ , hence in  $\bar{I}^*$  (respectively  $\tilde{I}^*$ ).

Consider more generally a smooth operator

$$C^\infty(K)^n \longrightarrow C^\infty(L, M),$$

with  $K, L$  and  $M$  manifolds. Replacing the codomain in (1.6) by

$$C^\infty(\mathbb{R}^P, C^\infty(L, M)) \simeq C^\infty(\mathbb{R}^P \times L, M)$$

yields a smooth map  $G/\mathbb{R}^P$  :

$$C^\infty(\mathbb{R}^P \times K)^n \longrightarrow C^\infty(\mathbb{R}^P \times L, M).$$

With  $\tilde{\cdot}$  denoting closure for any of the three topologies under consideration (discrete, Frechet, Stone), and with  $f_i, g_i \in C^\infty(\mathbb{R}^P \times K)$  as before we have

THEOREM 1.7'. If  $f_i - g_i \in \tilde{I}^*$  ( $i = 1, \dots, n$ ), we have

$$(1.8) \quad G/\mathbb{R}^P(f_1, \dots, f_n) \equiv G/\mathbb{R}^P(g_1, \dots, g_n) \text{ mod } \tilde{I}^*(M).$$

Proof. The conclusion (1.8) means 'weak congruence' of course. So let  $\phi: M \rightarrow \mathbb{R}$  be smooth, and apply Theorem 1.5 (for the discrete case) or Theorem 1.7 to the smooth operator

$$C^\infty(K)^n \xrightarrow{G} C^\infty(L, M) \xrightarrow{\phi_*} C^\infty(L).$$

### 2. The functor E.

Recall that  $E$  denotes any of the well adapted toposes  $Z, F$  and  $G$  mentioned in the introduction. If  $M$  is a manifold and  $I \subseteq C^\infty(M)$ , we let  $\tilde{I}$  denote its closure in any of the three topologies (discrete, Frechet, Stone), according to whether we read  $Z, F$  or  $G$ , for  $E$ .

Similarly,  $\tilde{\otimes}$  denotes coproduct in the sites of definition of either; if  $A$  is in the site,  $\bar{A} \in E$  denotes the object it represents. Thus  $\bar{A} \times \bar{B} = (A \tilde{\otimes} B)^-$ .

Let  $J \subseteq C^\infty(\mathbb{R}^P)$  be a closed ideal,  $J = \tilde{J}$ . For any manifold  $K$ , we have

$$(2.1) \quad C^\infty(\mathbb{R}^n)/J \tilde{\otimes} C^\infty(K) \simeq C^\infty(\mathbb{R}^P \times K)/\tilde{J}^* ;$$

this requires a small argument, which we shall not reproduce here (and I thank E. Dubuc for convincing me of its truth in the  $G$  case), since we shall only need the result for  $K = \mathbb{R}^k$ , where it is evidently true.

If  $M$  and  $L$  are manifolds, the exponential object  $M^L \in E$  goes by the global sections functor  $\Gamma$  to the set  $C^\infty(L, M)$  of smooth maps. So a map ('operator')

$$N^K \xrightarrow{G} M^L$$

in  $E$  goes by  $\Gamma$  to an operator

$$C^\infty(K, N) \xrightarrow{\Gamma(G)} C^\infty(L, M)$$

which evidently is (plot-) smooth. A main result in Bruno [2] is that this process can be reversed when  $N = \mathbb{R}$  (he also has some inessential restrictions on  $K, L, M$ ). From Theorem 1.7' we get a generalization of this result to the case  $N = \mathbb{R}^n$  (obtained independently also by Moerdijk and Reyes):

**THEOREM 2.1.** *Let  $K, L$  and  $M$  be manifolds. To any smooth operator  $G$ :*

$$C^\infty(K, \mathbb{R}^n) \simeq C^\infty(K)^n \xrightarrow{G} C^\infty(L, M),$$

there is a unique map in  $E$

$$(\mathbb{R}^n)^K \xrightarrow{E(G)} M^L$$

with  $\Gamma(E(G)) = G$ .

**Proof.** Let  $A = C^\infty(\mathbb{R}^P)/J$  be an object in the site of definition of  $E$  (so  $J = \tilde{J}$ ). We must produce a set theoretic map

$$(\mathbb{R}^n)^K(A) \xrightarrow{\varepsilon_A} M^L(A)$$

natural in  $A$ . An element  $b$  on the left corresponds, by Yoneda, exponential adjointness, and (2.1), to an  $n$ -tuple of elements

$b_i \in C^\infty(\mathbb{R}^P \times K)/\tilde{J}^*$ . Let  $\beta_i \in C^\infty(\mathbb{R}^P \times K)$  be a representative of  $b_i$ ,

so that we have a smooth map  $\beta = (\beta_1, \dots, \beta_n): \mathbb{R}^n \times K \longrightarrow \mathbb{R}^n$ .

Consider

$$(2.2) \quad \gamma := G/\mathbb{R}^P(\beta) \in C^\infty(\mathbb{R}^P \times L, M).$$

We get a  $C^\infty$ -algebra map 'composing with  $\gamma$ '

$$C^\infty(M) \longrightarrow C^\infty(\mathbb{R}^P \times L).$$

If we choose different representatives  $\beta_i'$  for  $b_i$ , (so  $\beta_i' - \beta_i \in \tilde{J}^*$ ),

we get immediately from Theorem 1.7' that  $\gamma' \equiv \gamma \pmod{\tilde{J}^*(M)}$  (here  $\tilde{J}^* \subset C^\infty(\mathbb{R}^P \times L)$ ); expressing this fact in the style of (1.1), and then taking the corresponding 'dual' diagram in  $E$ , yields commutativity of

$$\bar{A} \times L \longrightarrow R^P \times L \begin{array}{c} \xrightarrow{\gamma} \\ \xrightarrow{\gamma'} \end{array} M,$$

so that  $b$  well-defines a map  $\bar{A} \times L \longrightarrow M$ , or, equivalently, an element of  $M^L(A)$ , as desired. Naturality in  $A$  is straightforward (at least, the construction was not un-natural). So the map  $E(G)$  in  $E$  is now declared to be the natural transformation with components  $\epsilon_A$ .

It is clear that  $\Gamma(E(G))$  is just  $G$ : put  $A = C^\infty(\mathbb{R}^0) = \mathbb{R}$ , and use  $G/\mathbb{R}^0 = G$  and (2.2).

The uniqueness assertion yet to be proved we separate out as a separate, slightly more general 'faithfulness' assertion, Proposition 2.2 below.

Recall that the unit interval  $[0,1]$  is represented in  $E$  by the ring  $C^\infty(\mathbb{R})/H$ , where  $H$  is the ideal of functions  $\mathbb{R} \longrightarrow \mathbb{R}$  that vanish on  $[0,1]$ .

**PROPOSITION 2.2.** *Let  $K$  and  $M$  be representable (in particular they may be manifolds), and let  $L$  be a manifold, or  $[0,1]$ . Then any two maps  $\psi_1, \psi_2$ :*

$$(R^n)^K \begin{array}{c} \xrightarrow{\quad} \\ \xrightarrow{\quad} \end{array} M^L$$

with  $\Gamma(\psi_1) = \Gamma(\psi_2)$  are equal.

**Proof.** Since  $M$  is a subobject of some  $R^m$ , we reduce immediately to the case  $M = R$ , and it suffices to prove that a map  $\psi: (R^n)^K \longrightarrow R^L$  with  $\Gamma(\psi) = 0$  is itself 0. Let  $\bar{A}$  be a representable object, and  $b: \bar{A} \longrightarrow (R^n)^K$ . Consideration of the exponential adjoint of  $b$ , and representability of  $K$  (and thus of  $\bar{A} \times K$ ) leads to the extension of  $b$  to some  $c: R^P \longrightarrow (R^n)^K$ , and it suffices to prove  $\psi \circ c = 0$ . Now  $\psi \circ c: R^P \longrightarrow R^L$  corresponds to a map  $\phi: R^P \times L \longrightarrow R$ , such that  $\phi(x, -): L \longrightarrow R$  is the zero map for all (global) points  $x \in \mathbb{R}^P$ , by assumption on  $\Gamma(\psi)$ . In particular, for any (global) point  $y \in L$ ,  $\phi(x, y) = 0$ , so  $\phi$  has  $\Gamma(\phi) = 0$ , and since manifolds are fully embedded into  $E$ ,  $\phi$  has to be 0, for the case when  $L$  is a manifold.

If  $L$  is the unit interval, we argue as follows: extend  $\phi: \mathbb{R}^P \times L \longrightarrow R$  into a  $\phi: \mathbb{R}^P \times R \longrightarrow R$ . The smooth function  $\phi: \mathbb{R}^P \times \mathbb{R} \longrightarrow \mathbb{R}$  has the property that for each  $x \in \mathbb{R}^P$ ,  $\phi(x, -)$  belongs to the ideal  $H$ , that is  $\phi(x, t) = 0 \ \forall x \in \mathbb{R}^P, \forall t \in [0, 1]$ . But by a deep result of Calderón-Qué- Reyes [16], this implies that  $\phi \in H^*$ , so in particular  $\phi \in \tilde{H}^*$ , which is equivalent to saying  $\phi = 0$ .

(The Proposition holds (with the same proof) for any  $L$  which is represented by an ideal with line determined extensions in the sense of Bruno [3], which by [3] is a Frechet closed ideal  $I$  such that also all  $I^*$  are Frechet closed)

### 3. Application to integration in the topos models.

Let  $G$  be a Lie group, and  $LG$  its tangent space at the neutral element  $e \in G$ . Consider the pair of operators

$$C^\infty(\mathbb{R}, LG) \begin{matrix} \xleftarrow{T} \\ \xrightarrow{S} \end{matrix} C^\infty(\mathbb{R}, G),$$

where  $T$  is the 'differentiation' operator which to  $g: \mathbb{R} \longrightarrow G$  associates  $f$  given by

$$(3.1) \quad f(t) = \left. \frac{d}{ds} \right|_{s=0} g(t+s) \cdot g(t)^{-1},$$

and where  $S$  to  $f: \mathbb{R} \longrightarrow LG$  associates the unique  $g$  satisfying (3.1) and  $g(0) = e$ . (It is a classical result that this  $S$  exists and is smooth in parameters. In fact, if  $G$  is a matrix group,  $g$  is the solution of a linear homogeneous differential (matrix-) equation with variable coefficients  $f$ .)

The result of the previous section apply to  $S$  since  $LG \approx \mathbb{R}^n$  (but not to  $T$ ). By Theorem 2.1, we get a map  $\sigma = E(S)$  with  $\Gamma(\sigma) = S$ . We also have a  $\tau$  in the other direction

$$LG^R \begin{matrix} \xleftarrow{\tau} \\ \xrightarrow{\sigma} \end{matrix} G^R,$$

namely 'synthetic differentiation', given by the synthetic analogue of (3.1), that is  $\tau(g) = f$  with  $f$  given by

$$(3.2) \quad f(t)(d) = g(t+d) \cdot g(t)^{-1} \quad \forall d \in D .$$

A standard argument, as in [7] III Theorem 3.2, shows that  $\Gamma(\tau) = T$ . Thus

$$\Gamma(\tau \circ \sigma) = \Gamma(\tau) \circ \Gamma(\sigma) = T \circ S = id ,$$

By the 'Faithfulness' Proposition 2.2,  $\tau \circ \sigma$  is the identity map on  $LG^R$ .

Let us identify the Kernel pair of  $\tau$  by a synthetic argument. Suppose  $g, h \in G^R$  have  $\tau(g) = \tau(h)$ . Define  $g^{-1} \cdot h \in G^R$  by

$$(3.3) \quad (g^{-1} \cdot h)(t) = g(t)^{-1} \cdot h(t) .$$

Then

$$\begin{aligned} \tau(g^{-1} \cdot h)(t)(d) &= g(t+d)^{-1} \cdot h(t+d) \cdot h(t)^{-1} \cdot g(t) \\ &= g(t+d)^{-1} \cdot \tau(h)(t)(d) \cdot g(t) \\ &= g(t+d)^{-1} \cdot \tau(g)(t)(d) \cdot g(t) \\ &= g(t+d)^{-1} \cdot g(t+d) \cdot g(t)^{-1} \cdot g(t) = e , \end{aligned}$$

so  $\tau(g^{-1} \cdot h) \equiv e$  or

$$(g^{-1} \cdot h)(t+d) = (g^{-1} \cdot h)(t) \quad \forall t \in R, d \in D .$$

From Proposition 3.1 below it follows that  $g^{-1} \cdot h$  is constant, that is there is a unique  $c \in G$  so that

$$(3.4) \quad h(t) = g(t) \cdot c .$$

(Conversely, if (3.4) holds, then clearly  $\tau(g) = \tau(h)$ .)

**PROPOSITION 3.1.** *Let  $M$  be a manifold. If  $f \in M^R$  has  $f(t+d) = f(t) \quad \forall t \in R \quad \forall d \in D$ , then  $f(t) = f(0) \quad \forall t \in R$ .*

**Proof.** Since there exists a monic  $M \longrightarrow R^m$  for some  $m$ , one quickly reduces the question to the case  $M = R$ . Let  $b: \bar{A} \longrightarrow R^R$  be an element at stage  $\bar{A}$ , and extend it, as in the proof of Proposition 2.2 to an element  $c: R^P \longrightarrow R^R$ . Taking exponential adjoints gives an actual map in

$$R^P \times R \longrightarrow R,$$

and the assumption gives  $\frac{\partial \gamma}{\partial t}(x, t) \equiv 0$ . The external map  $\Gamma(\gamma)$  corresponding to  $\gamma$  then has the same property, so  $\Gamma(\gamma) = \Gamma(\gamma)(x, 0)$ . But  $\Gamma$  is faithful on the subcategory  $Mf \subset E$ , so  $\gamma(x, t) = \gamma(x, 0) \quad \forall t$  holds internally.

With  $G$  a Lie group, and  $LG$  its Lie algebra, as above, we derive the following Theorem about  $G$ -valued integration:

**THEOREM 3.2.** *In  $E$  we have*

$$(3.5) \quad \forall f \in LG^R \quad \exists! g \in G^R \text{ with } g(0) = e \text{ and } g(t+d) \cdot g(t)^{-1} = f(t)(d) \quad \forall t \in R, \quad d \in D.$$

**Proof.** The (internal) map  $E(S) = \sigma$ , together with the fact that  $\tau \circ \sigma$  is the identity, gives the existence. The uniqueness is immediate from the above identification of the kernel pair of  $\tau$ .

The Theorem can be reformulated in terms of differential forms with values in the group  $G$ , in the sense of [8]:

**THEOREM 3.2.** *In  $E$  we have that any  $G$ -valued 1-form on  $R$  is exact (with primitive unique modulo right multiplication by a unique constant from  $G$ ).*

**Proof.** The 1-form  $w$  associates with any neighbour pair  $(x, y)$  of  $R$  an element  $w(x, y) \in G$ , with  $w(x, x) = e \quad \forall x$ . Now  $(x, y)$  is of the form  $(x, x+d)$  for a unique  $d \in D$ , so

$$d \longmapsto w(x, x+d)$$

defines for each  $x \in R$  a tangent vector at  $e \in G$ . So the information of  $w$  is equivalent to that of a curve  $R \longrightarrow LG$ . The equation (3.5) equivalent to

$$g(y) \cdot g(x)^{-1} = w(x, y)$$

for  $x$  and  $y = x+d$  any neighbour pair of  $R$ . So  $g$  is the primitive, witnessing exactness of  $w$ . The uniqueness assertion is clearly equivalent to the previous identification of the kernel pair of  $\tau$ . This proves the Theorem.

We next consider the more important case of Lie group valued integration of functions, defined on the unit interval  $[0, 1]$ . Let  $G$  and  $LG$  be a Lie group and its Lie algebra, as in Theorem 3.2.

**THEOREM 3.3.** *In  $E$  we have*

$$\forall f \in LG^{[0,1]} \exists! g \in G^{[0,1]} \text{ with } g(0) = e \text{ and}$$

$$g(t+d) \cdot g(t)^{-1} = f(t)(d) \quad \forall t \in [0,1] \quad \forall d \in D;$$

*equivalently,  $G$ -valued 1-forms on  $[0,1]$  are exact, with primitive unique modulo right multiplication by a unique constant from  $G$ .*

**Proof.** The restriction map  $LG^R \longrightarrow LG^{[0,1]}$  is epic, since  $LG \simeq R^n$  and  $[0,1] \longrightarrow R$  is a representable subobject. Equivalently, in a synthetic argument, we may assume that every  $[0,1] \longrightarrow LG$  may be extended to  $R \longrightarrow LG$ , and then the existence assertion follows immediately from the existence assertion in Theorem 3.2. To prove the uniqueness, it suffices to prove that if  $g, h \in G^R$  have

$$\tau(g) \Big|_{[0,1]} = \tau(h) \Big|_{[0,1]}, \text{ with } \tau \text{ the differentiation process of (3.2),}$$

then the function  $g \cdot h^{-1}$ , defined in (3.3) is constant on  $[0,1]$ . The same calculation as before yields

$$\tau(g^{-1} \cdot h) \Big|_{[0,1]} \cong e.$$

so the result will follow from the analogue of Proposition 3.1:

**PROPOSITION 3.4.** *Let  $M$  be a manifold. If  $f \in M^R$  has  $f(t+d) = f(t) \quad \forall t \in [0,1] \quad \forall d \in D$ , then  $f(t) = f(0) \quad \forall t \in [0,1]$ .*

**Proof.** As in the proof of Proposition 3.1, it suffices to consider the case  $M = R$ , and again, to consider a generalized element  $f$  of  $R^R$  at stage  $\bar{A} = R^P$ ,  $f: R^P \longrightarrow R^R$ . The exponential adjoint  $\gamma: R^P \times R \longrightarrow R$  satisfies by assumption

$$\frac{\partial \gamma}{\partial t}(x, t) = 0 \quad \forall x, \forall t \in [0,1],$$

so for  $\Gamma(\gamma): IR^P \times IR \longrightarrow IR$ , we have, for all  $x \in IR^P$ ,

$$\Gamma(\gamma)(x, t) - \Gamma(\gamma)(x, 0) = 0 \quad \forall t \in [0,1].$$

This means that the composite of  $f$  with the restriction map

$$(3.6) \quad R^P \longrightarrow R^R \longrightarrow R^{[0,1]}$$

has the property that  $\Gamma$  takes it to the zero map. By Proposition 2.2 (which here is really the Calderón-Qu&eacute;-Reyes result!), the map (3.6) itself is the zero map, and the validity of  $f(t) = f(0) \quad \forall t \in [0,1]$  follows.

We remark that specializing Theorem 3.3 to the case  $G = (R,+)$  gives the validity of the usual "integration axiom" of [13]. The validity of this for the topos  $\mathcal{F}$  was first proved in Belair [1], and for the topos  $\mathcal{G}$  was known to Reyes, Dubuc and Penon. For the "Cahiers topos"  $\mathcal{C}$  (terminology of [7]), the arguments of the present article require some modifications, since  $[0,1]$  is no longer representable; but the category of manifolds with boundary is nevertheless fully embedded in  $\mathcal{C}$  which should make the modification of the arguments easy. Anyway, for  $\mathcal{C}$ , we gave an independent proof of  $R$ -valued integration in [13], and this argument may be extended to give  $G$ -valued integration for  $\mathcal{C}$ , as pointed out in [8].

Let us also remark that the 'lifting' of smooth operators

$$C^\infty(K,N) \longrightarrow C^\infty(L,M)$$

to the Cahiers topos, in the case where  $N$  and  $M$  are vector spaces  $\mathbb{R}^n$  (or convenient vector spaces) alternatively may be seen as an immediate consequence of the full embedding of convenient vector spaces into  $\mathcal{C}$ , [11].

We finish by proving the validity of a simple comprehensive form of the Frobenius Theorem. Recall [8] that a  $G$ -valued 1-form  $w$  on a manifold  $M$  is a law which to each neighbour pair  $x,y$  of  $M$  associates an element  $w(x,y) \in G$  with  $w(x,x) = e$ , and that  $w$  is called closed if

$$w(y,z) \cdot w(x,y) = w(x,z)$$

whenever  $x,y$  and  $z$  are mutual neighbours. If  $f: M \longrightarrow G$  is a function,  $df$  is the 1-form on  $M$  given by

$$df(x,y) = f(y) \cdot f(x)^{-1},$$

and  $df$  is clearly closed; 1-forms of form  $df$  are called exact, and  $f$  is called a primitive of  $f$ .

Let  $\mathcal{E}$  be any of the well adapted topos models mentioned in the introduction.

**THEOREM 3.5.** *Let  $G$  be a Lie group, and  $M$  a connected, simply connected manifold\*. Then any closed  $G$ -valued 1-form on  $M$  is exact (with primitive unique modulo a unique constant  $\epsilon \in G$ ).*

**Proof.** By Theorem 3.3, the group  $G$  "admits integration" in the sense of [8] (6.1). The result then follows from loc.cit Theorem 7.2.
